# 6.1100

### **Unoptimized Code Generation**

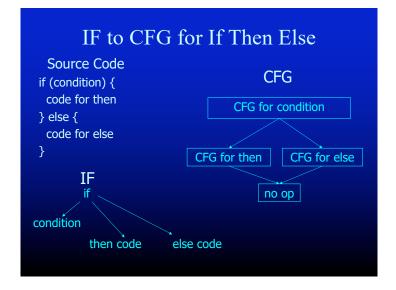

# Big Picture

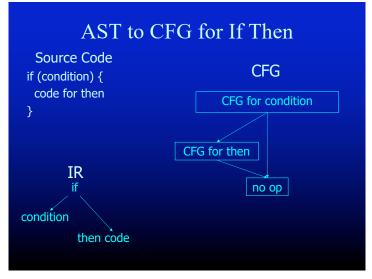

- Starting point structured IR
- Intermediate point CFG (control flow graph)
- Ending point Generated Assembly Code
- Emphasis on UNOPTIMIZED
- Do simplest possible thing for now
- Will treat optimizations separately

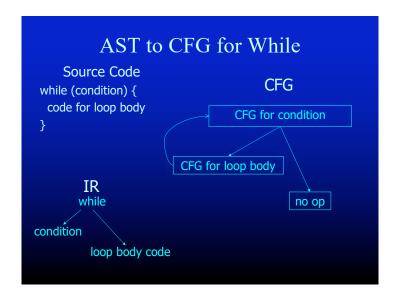

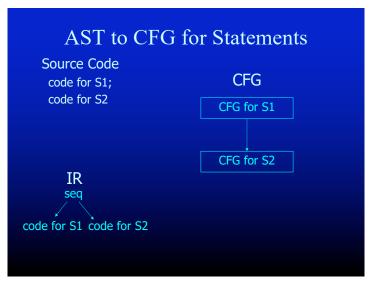

### Control Flow Graph

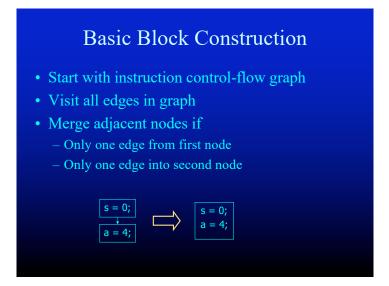

- Nodes Represent Computation
  - Each Node is a Basic Block
  - Basic Block is a Sequence of Instructions with
    - No Branches Out Of Middle of Basic Block
    - No Branches Into Middle of Basic Block
    - · Basic Blocks should be maximal
  - Execution of basic block starts with first instruction
  - Includes all instructions in basic block
- Edges Represent Control Flow

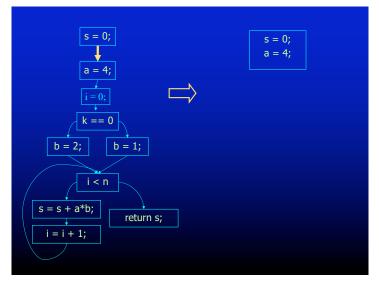

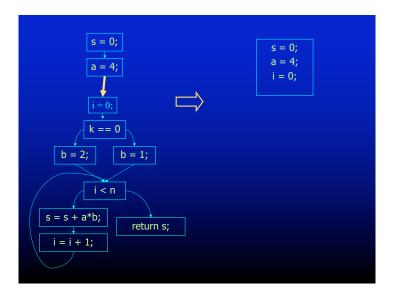

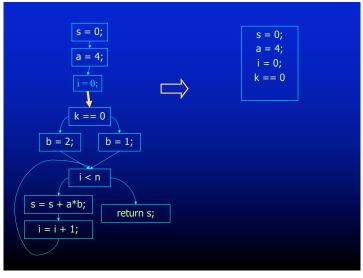

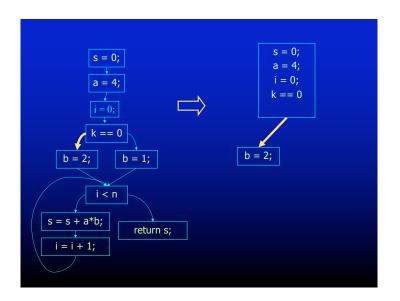

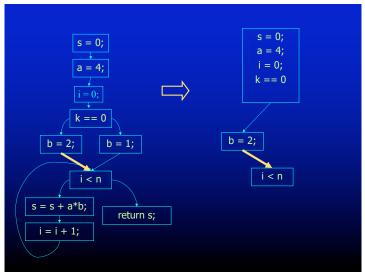

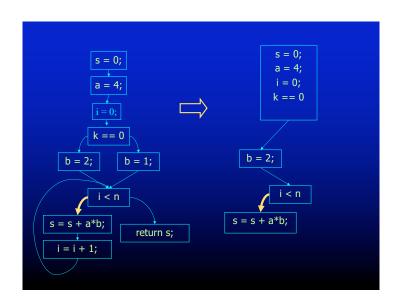

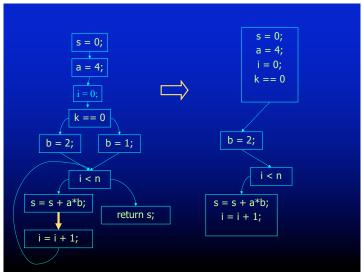

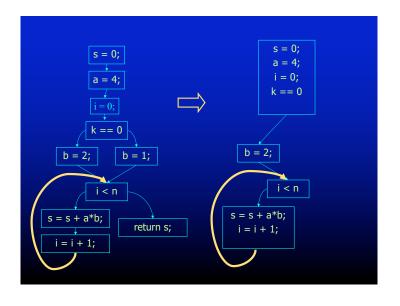

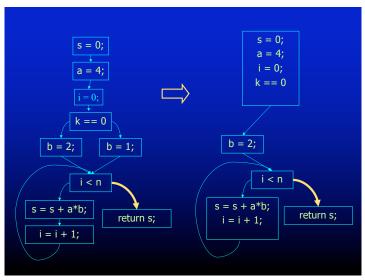

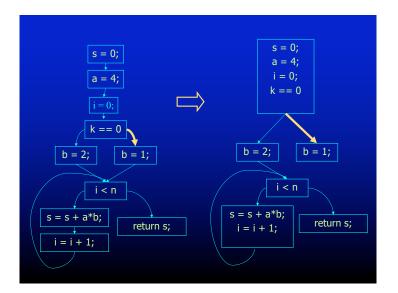

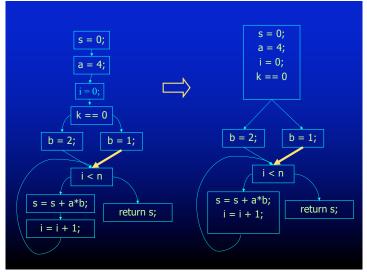

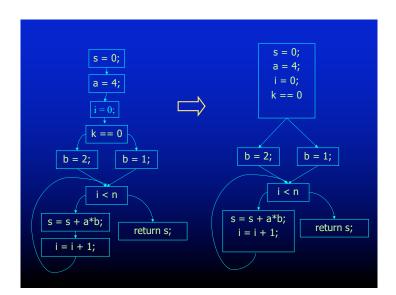

# Program Points, Split and Join **Points**

- One program point before and after each statement in
- Split point has multiple successors conditional branch statements only split points
- Merge point has multiple predecessors
- Each basic block
  - Either starts with a merge point or its predecessor ends with a split point
  - Either ends with a split point or its successor starts with a merge point

# Motivation For Short-Circuit Conditionals

Following program searches array for 0 element

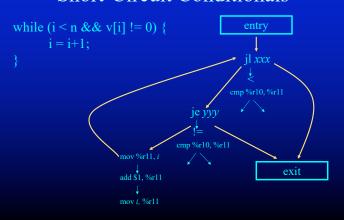

```
int i = 0;
while (i \le n \&\& a[i] != 0) {
 i = i + 1;
```

If i < n is false, should you evaluate a[i] != 0?

### **Short-Circuit Conditionals**

- In program, conditionals have a condition written as a boolean expression
  - $((i \le n) \&\& (v[i] != 0)) || i > k)$
- Semantics say should execute only as much as required to determine condition
  - Evaluate (v[i] != 0) only if (i < n) is true
  - Evaluate i > k only if ((i < n) & (v[i] != 0)) is
- Use control-flow graph to represent this shortcircuit evaluation

### **Short-Circuit Conditionals**

### More Short-Circuit Conditionals

# Routines for Destructuring Program Representation

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form

### shortcircuit(c, t, f)

generates short-circuit form of conditional represented by c if c is true, control flows to t node if c is false, control flows to f node

returns b - b is begin node for condition evaluation

new kind of node - nop node

# Destructuring Seq Nodes

### destruct(n

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

# **Destructuring Seq Nodes**

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

1: 
$$(b_x, e_x) = destruct(x)$$
;

$$\begin{array}{c}
\operatorname{seq} \\
\operatorname{x} \\
\operatorname{y}
\end{array}$$

# Destructuring Seq Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

1: 
$$(b_x,e_x) = destruct(x)$$
; 2:  $(b_y,e_y) = destruct(y)$ ;

### Destructuring Seq Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

- 1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;
- 3:  $next(e_x) = b_y$ ;

### Destructuring Seq Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

- $(b_x, e_x) = destruct(x); 2: (b_y, e_y) = destruct(y);$
- 3:  $next(e_x) = b_y$ ; 4: return  $(b_x, e_y)$ ;

### **Destructuring If Nodes**

### destruct(n

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $e \times y$ 

### **Destructuring If Nodes**

### destruct(n

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if e x y

1: 
$$(b_x,e_x) = destruct(x)$$
;

## Destructuring If Nodes

### destruct(n

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $c \times y$ 

1: 
$$(b_x,e_x) = destruct(x)$$
; 2:  $(b_y,e_y) = destruct(y)$ ;

$$b_x \xrightarrow{b_y} e_x$$

## Destructuring If Nodes

### destruct(n

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if c x y

- 1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;
- 3: e = new nop;

$$b_{x} \xrightarrow{b_{y}} e_{x}$$

$$b_{y} \xrightarrow{e} e_{y}$$

### Destructuring If Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $c \times v$ 

- 1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;
- 3: e = new nop; 4:  $next(e_x) = e$ ; 5:  $next(e_y) = e$ ;

## **Destructuring If Nodes**

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $e \times y$ 

- 1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;
- 3: e = new nop; 4:  $next(e_x) = e$ ; 5:  $next(e_y) = e$ ;
- 6:  $b_c = \text{shortcircuit}(c, b_x, b_y);$

# Destructuring If Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if e x y

- 1:  $(b_y,e_y) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;
- 3: e = new nop; 4:  $next(e_x) = e$ ; 5:  $next(e_y) = e$ ;
- 6:  $b_c = \text{shortcircuit}(c, b_x, b_y)$ ; 7: return  $(b_c, e)$ ;

# **Destructuring While Nodes**

# Nops In Destructured Representation while (i < n && v[i] != 0) { i = i+1;} mov %r11, 1 add \$1, %r11 mov i, %r11 mov i, %r11 mov i, %r11

# Linearizing CFG to Assembler

- Generate labels for edge targets at branches
  - Labels will correspond to branch targets
  - Can use code generation patterns for this
- Emit code for procedure entry
- Emit code for basic blocks
  - Emit code for statements/conditional expressions
  - Appropriately linearized
  - Jump/conditional jumps link basic blocks together
- Emit code for procedure exit

# **Overview of a modern ISA**

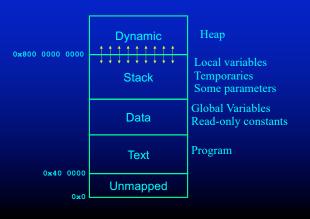

- Memory
- Registers
- ALU
- Control

# Overview of Computation

- Loads data from memory into registers
- Computes on registers
- Stores new data back into memory
- Flow of control determines what happens
- Role of compiler:
  - Orchestrate register usage
  - Generate low-level code for interfacing with machine

# Typical Memory Layout

## Concept of An Object File

- The object file has:
  - Multiple Segments
  - Symbol Information
  - Relocation Information
- Segments
  - Global Offset Table
  - Procedure Linkage Table
  - Text (code)
  - Data
  - Read Only Data
- To run program, OS reads object file, builds executable process in memory, runs process
- We will use assembler to generate object files

### **Basic Compilation Tasks**

- Allocate space for global variables (in data segment)
- For each procedure
  - Allocate space for parameters and locals (on stack)
  - Generate code for procedure
    - Generate procedure entry prolog
    - Generate code for procedure body
    - Generate procedure exit epilog

### Generate Code For Procedure Body

- Flatten expressions
  - Read program variables into temps before use
  - Use temps to have all ops of form

```
temp1 = temp2 op temp3
temp1 = temp2[temp3]
if (temp1 op temp2)
while (temp1 op temp2)
```

• For unoptimized code generation, apply code generation templates/patterns to flattened expressions

```
int values[20];
int sum(int n) {
    int i, t, temp1, temp2, temp3, temp4;
    i = 0;
    t = 0;
    temp1 = n;
    temp2 = 1;
    i = temp2;
    temp2 = 0;
    t = temp2;
    temp3 = i;
    temp4 = values[temp4];
    temp2 = temp3 + temp4;
    t = temp2;
    temp4 = temp1;
    temp4 = temp4;
    temp5 = i;
    temp6 = temp6;
    temp6 = i;
    temp6 = temp7;
    temp7 = i;
    temp8 = i;
    temp8 = i;
    temp8 = i;
    temp8 = i;
    temp9 = temp3 + temp6;
    i = temp2;
    }
    temp2 = temp3 + temp6;
    i = temp2;
}
```

```

```
Patterns for Unoptimized Generated Code

// temp3 = i
mov -16(%rbp), %rax
movq %rax, -40(%rbp)

// temp2 = temp3 + temp4
mov -40(%rbp), %rax
add -48(%rbp), %rax
movq %rax, -32(%rbp)

// temp4 = values[temp4]
mov -48(%rbp), %r10
mov values(, %r10, 8), %rax
movq %rax, -48(%rbp)
```

```
Code for If

// if (x >= 0) { then code} else { else code }

cmp $0, -48(%rbp) // check if x < 0
jl .elsebranch0
... then code
jmp.done0
.elsebranch0:
... else code
.done0
```

```
Array Bounds Check Code

cmp $0, -48(%rbp) //check if array index temp4 < 0
jl .boundsbad0
mov -48(%rbp), %rax
cmp $20, %rax //check if array index temp4 >= 20
jge .boundsbad0
jmp .boundsgood0 //perform array access
.boundsbad0:
mov -48(%rbp), %rdx
mov $8, %rcx
call .boundserror
.boundsgood0
```

```
Allocate space for global variables

Decaf global array declaration
   int values[20];

Assembler directive (reserve space in data segment)
   .comm_values,160,8

Name_Size_Alignment
```

### The Call Stack • Arguments 1 to 6 8\*n+16(%rbp) argument n are in: 16(%rbp) argument 7 %rdi, %rsi, %rdx, 8 (%rbp) Return address - %rcx, %r8, and %r9 Previous %rbp 0(%rbp) %rbp -8(%rbp) parameter 1 - marks the beginning of the current frame parameter n -8\*n-8(%rbp) %rsp local 1 0 (%rsp) marks top of stack -8\*(m+n)-8(%rbp) local m %rax 0(%rsp) Variable size return value

### Questions

- Why allocate activation records on a stack?
- Why not statically preallocate activation records?
- Why not dynamically allocate activation records in the heap?

### Allocate space for parameters/locals

- Each parameter/local has its own slot on stack
- Each slot accessed via %rbp negative offset
- Iterate over parameter/local descriptors
- Assign a slot to each parameter/local

### Generate procedure entry prologue

- Push base pointer (%rbp) onto stack
- Copy stack pointer (%rsp) to base pointer (%rbp)
- Decrease stack pointer by activation record size
- All done by: enter <stack frame size in bytes>, <lexical nesting level> enter \$48, \$0
- For now (will optimize later) move parameters to slots in activation record (top of call stack)

movq %rdi, -24(%rbp)

# x86 Register Usage

- 64 bit registers (16 of them)
  %rax, %rbx, %rcx, %rdx, %rdi, %rsi, %rbp, %rsp,
  %r8-%r15
- Stack pointer %rsp, base pointer %rbp
- Parameters
  - First six integer/pointer parameters in %rdi, %rsi, %rdx, %rex, %r8, %r9
  - Rest passed on the stack
- Return value
  - 64 bits or less in %rax
  - Longer return values passed on the stack

# Questions

- Why have %rbp if also have %rsp?
- Why not pass all parameters in registers?
- Why not pass all parameters on stack?
- Why not pass return value in register(s) regardless of size?
- Why not pass return value on stack regardless of size?

### Callee vs caller save registers

- Registers used to compute values in procedure
- Should registers have same value after procedure as before procedure?
  - Callee save registers (must have same value) %rsp, %rbx, %rbp, %r12-%r15
  - Caller save registers (procedure can change value) %rax, %rcx, %rdx, %rsi, %rdi, %r8-%r11
- Why have both kinds of registers?

### Generate procedure call epilogue

- Put return value in %rax mov -32(%rbp), %rax
- Undo procedure call
  - Move base pointer (%rbp) to stack pointer (%rsp)
  - Pop base pointer from caller off stack into %rbp
  - Return to caller (return address on stack)
  - All done by

leave

ret

### Procedure Linkage •Save caller-saved registers Set up arguments • Registers (1-6) Standard procedure linkage Stack (7-N) procedure p **Prolog:** •Push old frame pointer prolog procedure q Save callee-saved registers prolog •Make room for parameters, temporaries, and locals pre-call Epilog: •Restore callee-saved registers post-return epiloa •Pop old frame pointer •Store return value Post-return: epilog •Restore caller-saved registers Pop arguments

# Generate code for procedure body Evaluate expressions with a temp for each subexpression Temps stored on stack %rax as working register

Apply code generation templates temp = vartemp = temp op temp var = temp

# Generate code for procedure body

Evaluate expressions with a temp for each subexpression

```
Temps stored on stack
                           %rax as working register
                            Apply code generation templates
                            temp = var
                             temp = temp op temp
                             var = temp
mov -32(%rbp), %rax
movq %rax, -16(%rbp)
```

# **Evaluating Expression Trees**

### Flat List Model

- The idea is to linearize the expression tree
- Left to Right Depth-First Traversal of the expression tree
  - Allocate temporaries for intermediates (all the nodes of the tree)
    - New temporary for each intermediate
    - All the temporaries on the stack (for now)
- Each expression is a single 3-addr op

  - Code generation for the 3-addr expression
    - Load y into register %rax
    - Perform op z, %rax
    - Store %rax to x

Another option Load y into register %rax Store %rax to x

### Issues in Lowering Expressions

- Map intermediates to registers?
  - registers are limited
    - When the tree is large, registers may be insufficient ⇒ allocate space in the stack
- · Very inefficient
  - too many copies
  - don't worry, we'll take care of them in the optimization passes
  - keep the code generator very simple

## Generate code for procedure body

### Basic Ideas

- •Temps, locals, parameters all have a "home" on stack
- •When compute, use %rax as working storage
- •All subexpressions are computed into temps
- •For each computation in expression
  - Fetch first operand (on stack) into %rax
  - Apply operator to second operand (on stack) and %rax
  - Result goes back into %rax
  - Store result (in %rax) back onto stack

### Generate code for procedure body

### Accessing an array element

```
//array access temp1 = values[temp0]
mov array index in temp0, %r10
```

mov values[array index in %r10], %rax

movq %rax, temp1

%r10 as array index register

%rax as working register

Apply code generation template

# Generate code for procedure body

### Accessing an array element

//array access temp1 = values[temp0]

mov -48(%rbp), %r10

mov values(, %r10, 8), %rax

movq %rax, -48(%rbp)

%r10 as array index register

%rax as working register

Apply code generation template

## Generate code for procedure body

### Array bounds checks (performed before array access)

```
check if array index < 0
```

il boundshad0

check if array index >= array bound

jge .boundsbad0

jmp .boundsgood0 //perform array access

.boundsbad0:

first parameter is array index

second parameter is array element size

call .boundserror

.boundsgood0:

perform array access

## Generate code for procedure body

### Array bounds checks (performed before array access)

```
cmp 0, -48(\%rbp) //check if array index temp4 < 0
```

jl .boundsbad0

mov -48(%rbp), %rax

cmp \$20, %rax //check if array index temp4 >= 20

ige .boundsbad0

jmp .boundsgood0 //perform array access

### .boundsbad0:

mov -48(%rbp), %rdx

%rax as working register

Apply code generation template

call .boundserror

.boundsgood0: //array access to values[temp4]

mov -48(%rbp), %r10

mov values(, %r10, 8), %rax

movq %rax, -48(%rbp)

### Generate code for procedure body

```
Control Flow via comparisons and jumps
```

//if (condition) { code } else { code } compute condition

if condition not true to jump to .FalseCase

.TrueCase:

// code for true case

jmp .EndIf // skip else case

.FalseCase:

// code for else case

.EndIf:

// code for after if

### Generate code for procedure body

### Control Flow via comparisons and jumps

.CheckCondition:

// code for true case jmp .EndIf // skip else case

.FalseCase:

// code for else case

.EndIf: // continuation after if

Code generation template for if then else (conditional branch) Stores condition explicitly, may be more debuggable

### Generate code for procedure body

### Control Flow via comparisons and jumps

%rax as working register Apply code generation template

Code generation template for

if then else (conditional branch)

jge .BasicBlock8

.BasicBlock8:

.BasicBlock9:

ine .BasicBlock11

.BasicBlock10:

jmp .BasicBlock12 // skip else case

BasicBlock11:

# Code For Conditional Branch in **CFG**

- Each basic block has a label
- Each conditional branch in CFG has
  - True edge (goes to basic block with label LT)
  - False edge (goes to basic block with label LF)
- Emitted code for CFG tests condition
  - If true, jump to LT
  - If false, jump to LF
- Emit all basic blocks (in some order), jumps link everything together

# Quick Peephole Optimization

- Emitted code can look something like:
  - .BasicBlock0

.BasicBlock0:

• In this case can remove jmp instruction

### Guidelines for the code generator

- Lower the abstraction level slowly
  - Do many passes, that do few things (or one thing)
  - Easier to break the project down, generate and debug
- Keep the abstraction level consistent
  - IR should have 'correct' semantics at all time
  - At least you should know the semantics
  - You may want to run some of the optimizations between the passes.
- Write sanity checks, consistency checks, use often

### Guidelines for the code generator

- Do the simplest but dumb thing
  - it is ok to generate 0 + 1\*x + 0\*y
  - Code is painful to look at; let optimizations improve it
- Make sure you know want can be done at...
  - Compile time in the compiler
  - Runtime using generated code

### Guidelines for the code generator

- Remember that optimizations will come later
  - Let the optimizer do the optimizations
  - Think about what optimizer will need and structure your code accordingly
  - Example: Register allocation, algebraic simplification, constant propagation
- Setup a good testing infrastructure
  - regression tests
    - If a input program creates a bug, use it as a regression test
  - Learn good bug hunting procedures
    - Example: binary search, delta debugging

# Machine Code Generator Should...

- Translate all the instructions in the intermediate representation to assembly language
- Allocate space for the variables, arrays etc.
- Adhere to calling conventions
- Create the necessary symbolic information

# **Assembly language**

- Advantages
  - Simplifies code generation due to use of symbolic instructions and symbolic names
  - Logical abstraction layer
  - Multiple Architectures can describe by a single assembly language
    - ⇒ can modify the implementation
    - macro assembly instructions
- Disadvantages
  - Additional process of assembling and linking
  - Assembler adds overhead

# **Assembly language**

- Relocatable machine language (object modules)
  - all locations(addresses) represented by symbols
  - Mapped to memory addresses at link and load time
  - Flexibility of separate compilation
- · Absolute machine language
  - addresses are hard-coded
  - simple and straightforward implementation
  - inflexible -- hard to reload generated code
  - Used in interrupt handlers and device drivers

## Concept of An Object File

- The object file has:
  - Multiple Segments
  - Symbol Information
  - Relocation Information
- Segments
  - Global Offset Table
  - Procedure Linkage Table
  - Text (code)
  - Data
  - Read Only Data
- To run program, OS reads object file, builds executable process in memory, runs process
- We will use assembler to generate object files

# Overview of a modern ISA

- Memory
- Registers
- ALU
- Control

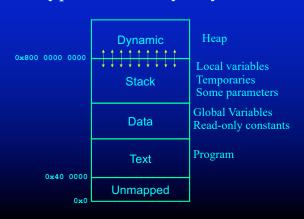

### From IR to Assembly

- Data Placement and Layout
  - Global variables
  - Constants (strings, numbers)
  - Object fields
  - Parameters, local variables
  - Temporaries
- Code
  - Read and write data
  - Compute
  - Flow of control

# **Typical Memory Layout**

# Global Variables

struct { int x, y; double z; } b;
int g;
int a[10];

Assembler directives (reserve space in data segment)
.comm \_a,40,4 ## @a
.comm \_b,16,3 ## @b
.comm \_g,4,2 ## @g

Name Size Alignment

### Addresses

### Reserve Memory

## @a

## @b

## (a)g

### Define 3 constants

- a address of a in data segment
- b address of b in data segment
- \_g address of g in data segment

### Struct and Array Layout

- struct { int x, y; double z; } b;
  - Bytes 0-1: x
  - Bytes 2-3: y
  - − Bytes 4-7: z
- int a[10]
  - Bytes 0-1: a[0]
  - Bytes 2-3: a[1]
  - **–** ...
  - Bytes 18-19: a[9]

# **Dynamic Memory Allocation**

typedef struct { int x, y; } PointStruct, \*Point;
Point p = malloc(sizeof(PointStruct));

What does allocator do?

returns next free big enough data block in heap

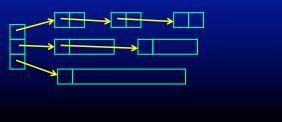

appropriately adjusts heap data structures

### Some Heap Data Structures

• Free List (arrows are addresses)

• Powers of Two Lists

# Getting More Heap Memory

Scenario: Current heap goes from 0x800 0000 000- 0x810 0000 0000

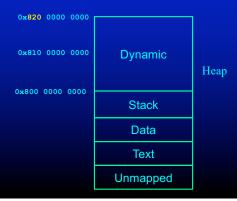

Need to allocate large block of memory

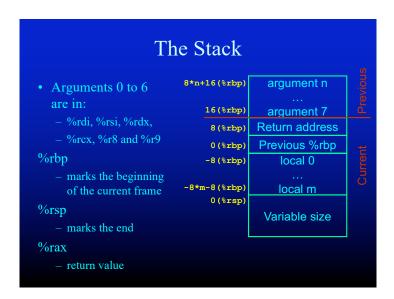

No block that large available

# Getting More Heap Memory

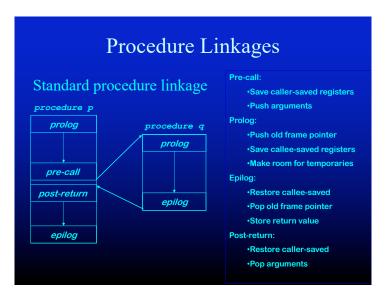

Solution: Talk to OS, increase size of heap (sbrk)
Allocate block in new heap

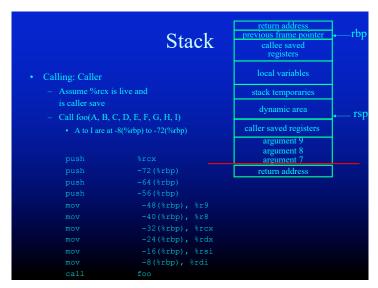

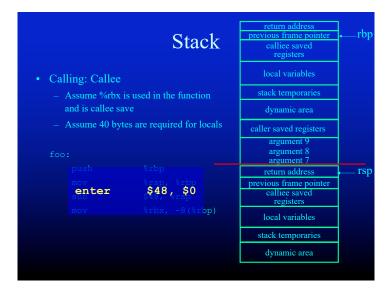

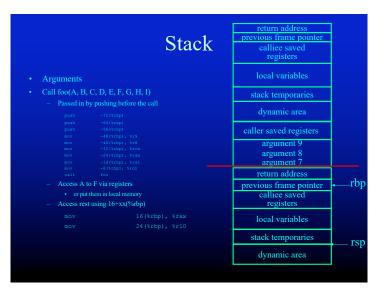

# Question:

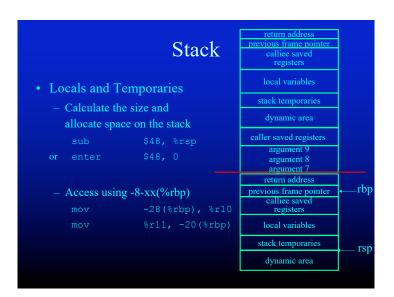

• Why use a stack? Why not use the heap or preallocated in the data segment?

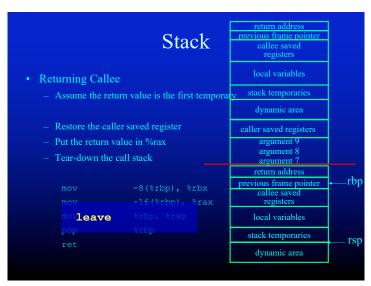

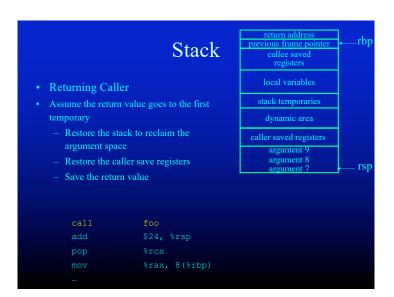

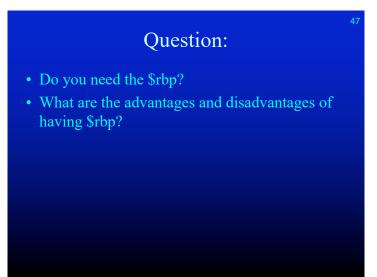

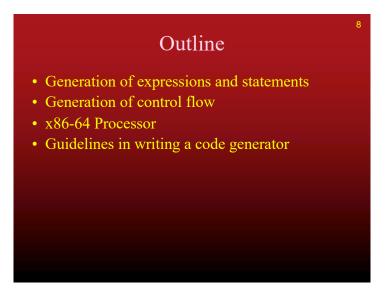

### **Expressions**

- Expressions are represented as trees
  - Expression may produce a value
  - Or, it may set the condition codes (boolean exprs)
- How do you map expression trees to the machines?
  - How to arrange the evaluation order?
  - Where to keep the intermediate values?
- Two approaches
  - Stack Model
  - Flat List Model

## Evaluating expression trees

- Stack model
  - Eval left-sub-treePut the results on the stack
  - Eval right-sub-treePut the results on the stack
  - Get top two values from the stack perform the operation OP put the results on the stack

### **Evaluating Expression Trees**

- Flat List Model
  - The idea is to linearize the expression tree
  - Left to Right Depth-First Traversal of the expression tree
    - Allocate temporaries for intermediates (all the nodes of the tree)
      - New temporary for each intermediate
      - All the temporaries on the stack (for now)
  - Each expression is a single 3-addr op
    - x = y op z
    - Code generation for the 3-addr expression
      - Load y into register %rax
      - Perform op z, %rax
      - Store %rax to x

## Issues in Lowering Expressions

- Map intermediates to registers?
  - registers are limited
    - when the tree is large, registers may be insufficient ⇒ allocate space in the stack
- No machine instruction is available
  - May need to expand the intermediate operation into multiple machine ops.
- Very inefficient
  - too many copies
  - don't worry, we'll take care of them in the optimization passes
  - keep the code generator very simple

### What about statements?

- Assignment statements are simple
  - Generate code for RHS expression
  - Store the resulting value to the LHS address
- But what about conditionals and loops?

### Outline

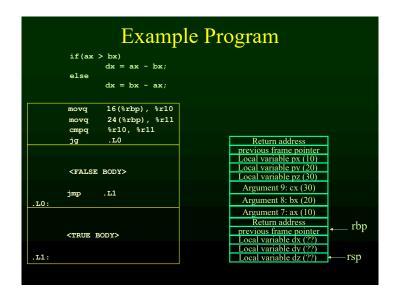

- Generation of statements
- Generation of control flow
- Guidelines in writing a code generator

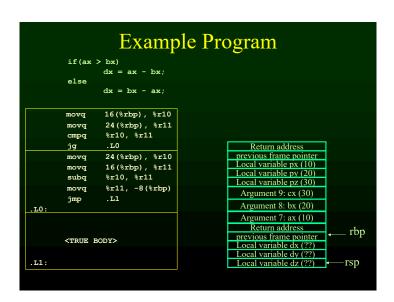

28

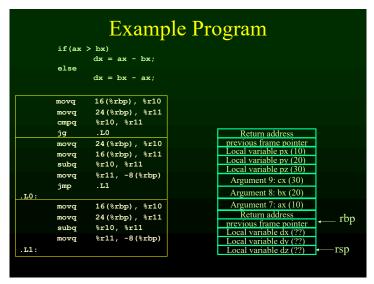

# Two Techniques

- Template Matching
- Short-circuit Conditionals
- Both are based on structural induction
  - Generate a representation for the sub-parts
    - Combine them into a representation for the whole

### **Example Program** if(ax > bx) dx = ax - bx;else dx = bx - ax;<do test> joper .L0 Return address previous frame pointer Local variable px (10) Local variable py (20) Local variable pz (30) <FALSE BODY> Argument 9: cx (30) Argument 8: bx (20) .L0: Argument 7: ax (10) Return address rbp previous frame pointe Local variable dx (??) <TRUE BODY> Local variable dy (??) Local variable dz (??) .L1:

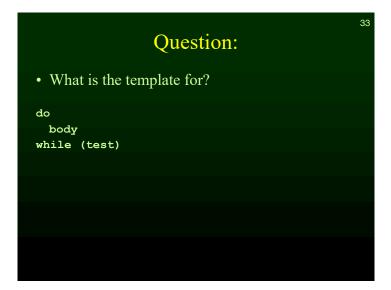

# Template for while loops while (test) body

```
Template for while loops
                   lab_cont:
while (test)
                         <do the test>
                         joper lab_body
  body
                             lab_end
                         jmp
                   lab_body:
                         <body>
                        jmp
                             lab cont
                   lab end:
 • An optimized template
                   lab_cont:
                         <do the test>
                         joper lab end
                         <body>
                              lab_cont
                         jmp
                   lab end:
```

```
Question:

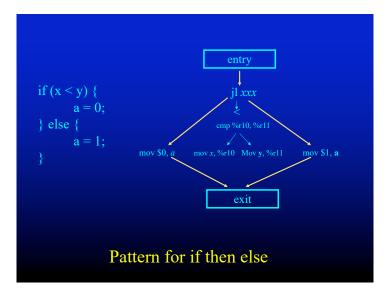

• What is the template for?

do
   body
while (test)

lab_begin:
   <body>
   <do test>
   joper lab_begin
```

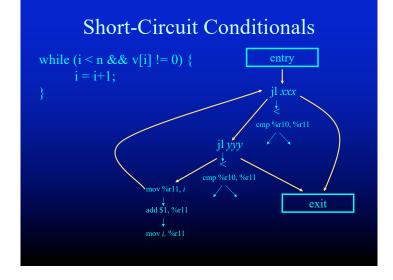

# Control Flow Graph (CFG)

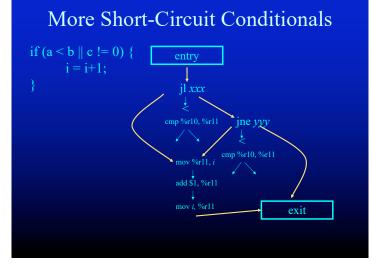

- Starting point: high level intermediate format, symbol tables
- Target: CFG
  - CFG Nodes are Instruction Nodes
  - CFG Edges Represent Flow of Control
  - Forks At Conditional Jump Instructions
  - Merges When Flow of Control Can Reach A Point Multiple Ways
  - Entry and Exit Nodes

### **Short-Circuit Conditionals**

- In program, conditionals have a condition written as a boolean expression
   ((i < n) && (v[i] != 0)) || i > k)
- Semantics say should execute only as much as required to determine condition
  - Evaluate (v[i] != 0) only if (i < n) is true
  - Evaluate i > k only if  $((i \le n) \&\& (v[i] != 0))$  is false
- Use control-flow graph to represent this short-circuit evaluation

# Routines for Destructuring Program Representation

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form

### shortcircuit(c, t, f)

generates short-circuit form of conditional represented by c if c is true, control flows to t node if c is false, control flows to f node returns b - b is begin node for condition evaluation

new kind of node - nop node

## Destructuring Seq Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

# Destructuring Seq Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

1:  $(b_x,e_x) = destruct(x);$ 

### Destructuring Seq Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;

### Destructuring Seq Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

1:  $(b_x, e_x) = destruct(x)$ ; 2:  $(b_y, e_y) = destruct(y)$ ;

3:  $next(e_x) = b_y$ ;

### Destructuring Seq Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form seq x y

1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;

3:  $next(e_x) = b_y$ ; 4:  $return(b_x, e_y)$ ;

## Destructuring If Nodes

### destruct(n

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $e \times y$ 

## Destructuring If Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $c \times y$ 

1:  $(b_x,e_x) = destruct(x)$ ;

### Destructuring If Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if c x y

1: 
$$(b_x,e_x) = destruct(x)$$
; 2:  $(b_y,e_y) = destruct(y)$ ;

$$b_x \rightarrow c_x$$
 $b_y \rightarrow c_y$ 

# Destructuring If Nodes

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $e \times y$ 

- 1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;
- 3: e = new nop;

# Destructuring If Nodes

### destruct(n

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $e \times y$ 

- 1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;
- 3: e = new nop; 4:  $next(e_x) = e$ ; 5:  $next(e_y) = e$ ;

### Destructuring If Nodes

### destruct(n

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $e \times y$ 

- 1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;
- 3: e = new nop; 4:  $next(e_x) = e$ ; 5:  $next(e_y) = e$ ;
- 6:  $b_c = \text{shortcircuit}(c, b_x, b_y);$

## **Destructuring If Nodes**

### destruct(n)

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form if  $e \times y$ 

- 1:  $(b_x,e_x) = destruct(x)$ ; 2:  $(b_y,e_y) = destruct(y)$ ;
- 3: e = new nop; 4:  $next(e_x) = e$ ; 5:  $next(e_y) = e$ ;
- 6:  $b_c = \text{shortcircuit}(c, b_x, b_y)$ ; 7: return  $(b_c, e)$ ;

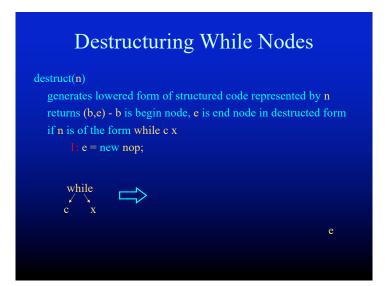

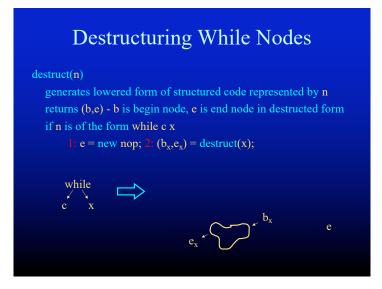

## **Destructuring While Nodes**

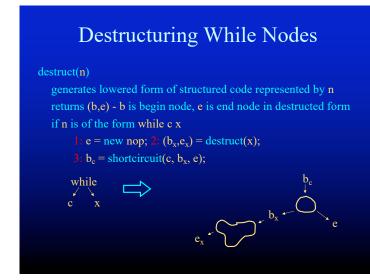

### destruct(n

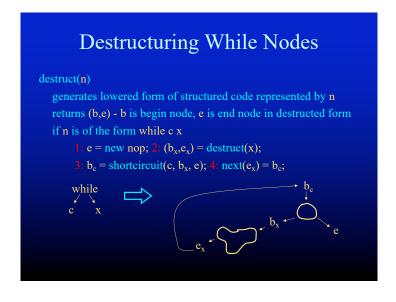

generates lowered form of structured code represented by n returns (b,e) - b is begin node, e is end node in destructed form if n is of the form while c x

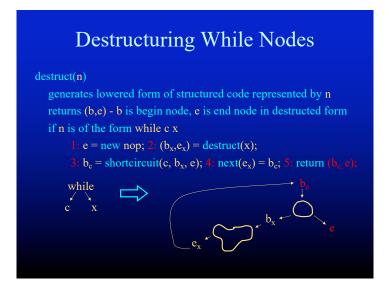

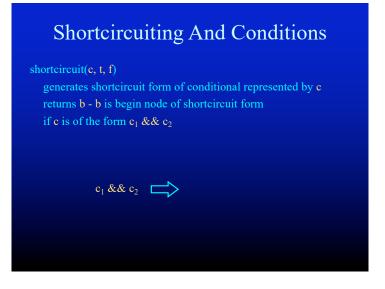

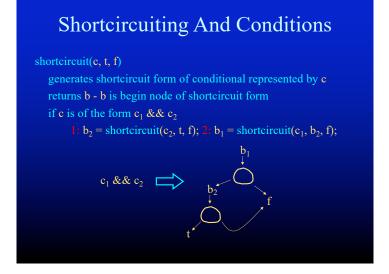

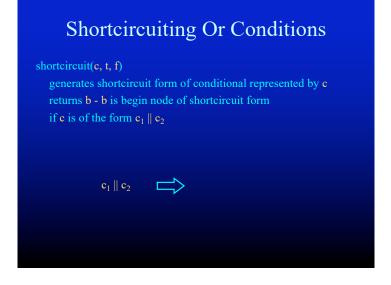

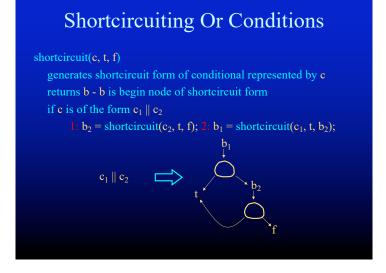

# Shortcircuiting And Conditions shortcircuit(c, t, f) generates shortcircuit form of conditional represented by c returns b - b is begin node of shortcircuit form if c is of the form $c_1 \&\& c_2$ It $b_2 = \text{shortcircuit}(c_2, t, f)$ ;

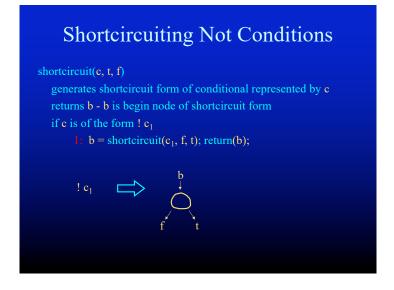

# Shortcircuiting And Conditions shortcircuit(e, t, f) generates shortcircuit form of conditional represented by c returns b - b is begin node of shortcircuit form if c is of the form c<sub>1</sub> && c<sub>2</sub> 1: b<sub>2</sub> = shortcircuit(c<sub>2</sub>, t, f); 2: b<sub>1</sub> = shortcircuit(c<sub>1</sub>, b<sub>2</sub>, f); 3: return (b<sub>1</sub>); c<sub>1</sub> && c<sub>2</sub>

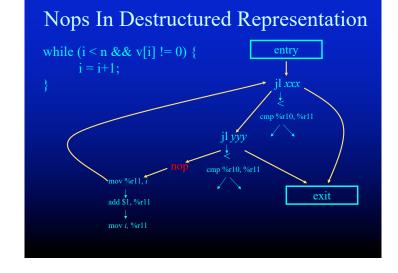

# Shortcircuiting Or Conditions shortcircuit(e, t, f) generates shortcircuit form of conditional represented by c returns b - b is begin node of shortcircuit form if c is of the form $c_1 \parallel c_2$ 1: $b_2 = \text{shortcircuit}(c_2, t, f)$ ;

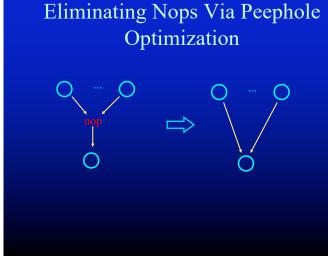

# Shortcircuiting Or Conditions shortcircuit(c, t, f) generates shortcircuit form of conditional represented by c returns b - b is begin node of shortcircuit form if c is of the form c<sub>1</sub> || c<sub>2</sub> 1: b<sub>2</sub> = shortcircuit(c<sub>2</sub>, t, f); 2: b<sub>1</sub> = shortcircuit(c<sub>1</sub>, t, b<sub>2</sub>); 3: return (b<sub>1</sub>); c<sub>1</sub> || c<sub>2</sub>

# Computed Conditions shortcircuit(e, t, f) generates shortcircuit form of conditional represented by c returns b - b is begin node of shortcircuit form if c is of the form $e_1 < e_2$ $e_1 < e_2$

# Linearizing CFG to Assembler

- Generate labels for edge targets at branches
  - Labels will correspond to branch targets
  - Can use patterns for this
- Generate code for statements/conditional expressions
- Generate code for procedure entry/exit

# **Exploring Assembly Patterns**

# Outline

- Generation of statements
- Generation of control flow
- x86-64 Processor
- Guidelines in writing a code generator
